

Chapter 02 Cognitive Transitions

1. Which of the following is not one of the five chief changes in cognition during adolescence?
- A. multidimensional thought
 - B. metacognition
 - C. abstract reasoning
 - D. increased imagination**

Difficulty: Moderate

Page: 43

4. Dan, an adolescent, has more developed cognitive skills than his 6-year-old brother Timmy because Timmy's thinking is:
- A. in general, bound to what he can directly observe.**
 - B. moving easily between specific and abstract ideas.
 - C. systematically generating alternative possibilities and explanations.
 - D. comparing what he actually observes with what he believes is possible.

APA LO: 1.3

Bloom's: Apply

Difficulty: Moderate

Page: 44

5. Which term below allows individuals to suspend their beliefs about something in order to argue in the abstract?
- A. hypothetical thinking**
 - B. social cognition
 - C. mutual perspective-taking
 - D. impression formation

Accessibility: Keyboard Navigation

APA LO: 2.4

Bloom's: Evaluate

Difficulty: Moderate

Page: 44

6. Which of the following does not support adolescents' improved ability to use deductive reasoning, as described by the text?
- A. the ability to inhibit a prepotent response
 - B. the ability to stop oneself from acting automatically

- C. the ability to make an inference based on accumulated evidence
D. the ability to recognize when a question cannot be answered with certainty

8. Joey enjoys playing the devil's advocate and is always stirring up discussions with his contrary positions. This ability is one aspect of:
A. hypothetical thinking.
B. social cognition.
C. mutual perspective-taking.
D. impression formation.

Accessibility: Keyboard Navigation

APA LO: 1.3

Bloom 's: Apply

Difficulty: Moderate

Page: 44

9. The ability to see beyond what is directly observable and reason in terms of what might be possible is called:
A. theory of mind.
B. hypothetical thinking.
C. imaginary audience.
D. formal operations.

Accessibility: Keyboard Navigation

APA LO: 1.2

Bloom 's: Evaluate

Difficulty: Basic

Page: 44

10. All of the following are aspects of metacognition, except:
A. conserving mental resources.
B. thinking about thinking.
C. appraising comprehension.
D. managing thinking.

APA LO: 1.1
Bloom's: Remember
Difficulty: Basic
Page: 45-46

21. Dave knows that kids who drink and drive sometimes get killed, but he believes that he is somehow immune to having such a terrible thing happen to him. Dave's belief is an example of:

- A. the imaginary audience.
- B. a personal fable.**
- C. social cognition.
- D. metacognition.

Accessibility: Keyboard Navigation
APA LO: 1.3
Bloom's: Apply
Difficulty: Moderate
Page: 45-46

22. The ability to think about one's own thoughts is called:

- A. hypothetical think.
- B. egocentric logic.
- C. metacognition.**
- D. social cognition.

Accessibility: Keyboard Navigation
APA LO: 1.2
Bloom's: Remember
Difficulty: Basic
Page: 46

23. All of the following are indicators of metacognition, except:

- A. introspection.
- B. self-consciousness.
- C. using mental strategies to remember something.
- D. deductive reasoning.**

Accessibility: Keyboard Navigation
APA LO: 2.1
Bloom's: Evaluate
Difficulty: Moderate
Page: 46

24. Research testing Elkind's theory of adolescent egocentrism has found that certain aspects:
- A. peak at age 12 and then drastically decline.
 - B. may remain present throughout the adolescent and adult years.**
 - C. are virtually a nonexistent phenomenon in adolescence or adulthood.
 - D. are less prevalent among college students.

Accessibility: Keyboard Navigation
APA LO: 2.4
Bloom's: Analyze
Difficulty: Difficult
Page: 46

25. The text suggests that _____ are not a good explanation of adolescent egocentrism.
- A. cognitive deficiencies**
 - B. emotional reasons
 - C. social reasons
 - D. the impact of other people's opinions

26. The extreme skepticism observed in many adolescents is most likely a result of:
- A. seeing knowledge as relative rather than as absolute.**
 - B. thinking in terms of what's possible rather than what's real.
 - C. thinking about the process of thinking.
 - D. viewing reality in terms of multiple dimensions.

Accessibility: Keyboard Navigation

Bloom 's: Understand
Difficulty: Difficult
Page: 47

31. Dr. Martino argues that development proceeds in stages and that each stage is marked by fairly consistent behavior. Then, as the child's biological development progresses and new experiences are acquired, a shift occurs and development breaks through to the next level. Dr. Martino's view is most consistent with that expressed by the:

- A. triarchic theory of intelligence.
- B. information-processing perspective.
- C. psychometric theory.
- D.** Piagetian perspective.

103. You join your friends for coffee and notice they are arguing about whether the Piagetian or the information-processing perspective offers a better explanation of cognitive development. They ask for your opinion, and you tell them that each is useful but each has limitations. You suggest a third approach that integrates the two perspectives. What do you tell your friends?

Piaget laid the groundwork to understand that cognition develops qualitatively, with different ways of reasoning and understanding the world from birth through adolescence. Awareness that abstract reasoning skills do not develop until adolescence has had a positive impact on education. Although not always used, particularly if tasks are not personally relevant, these skills enable the adolescent to think in terms of possibilities, multidimensionally, and metacognitively. However, research suggests that the skills develop gradually and continuously, not in abrupt stages, and the Piagetian approach is not clear about which specific aspects of intellectual development are most important. The information-processing view explains quantitative increases in cognitive skills (e.g., memory, attention, processing speed, organizational strategies, and metacognition), but omits the fact that adolescents do think in a way that is qualitatively different from children. An integrative approach says that although cognitive development proceeds in discrete stages, the process is linked to physical changes in the brain and is better studied in terms of the cognitive components (e.g., memory, attention) used by information-processing theorists. Paul Klaczynski's integrative approach examines both the analytic and intuitive cognitive systems to explain why, despite our cognitive skills, our behavior is often so illogical.

Key Points:

- a) Piaget's theory has had a positive impact on education.
- b) Research suggests gradual, rather than discrete, development.
- c) Piaget was not clear about which aspects of cognition were most important.
- d) Information processing offers specific information about aspects of cognition.
- e) Information processing ignores qualitative changes.

- f) Integrative approaches incorporate qualitative and quantitative concepts.
- g) Integrative approaches ask useful questions, such as why we don't use our skills in everyday decision making.

104. Mr. Goldberg, a high school teacher, approaches you (a brilliant adolescent psychologist) regarding two of his students. He is concerned about their behavior and hopes you can explain what is going on. One student, Sharon, occasionally engages in unprotected sex. The other student, Michael, constantly wears pants to hide what he believes are skinny legs. Using David Elkind's research results, how would you characterize Sharon's behavior? How would you characterize Michael's behavior? Be sure to justify your answer.

These two phenomena result from Elkind's theory of adolescent egocentrism. Sharon's behavior is a classic example of what Elkind refers to as the personal fable. She believes that what she does and what happens to her is unique. Her belief is that nothing will happen to her if she occasionally engages in unprotected sex. Michael's behavior is related to what Elkind refers to as the imaginary audience. He believes that everyone's thoughts are about him, that they are constantly looking at him (as if he were on stage).

Key Points:

- a) David Elkind's theory of adolescent egocentrism
- b) Sharon's behavior may be characterized by the personal fable.
- c) Michael exhibits portions of the imaginary audience phenomenon.

105. Your roommate is taking an anatomy class and has noticed differences in the brains of younger and older rats. She knows ethical reasons prohibit euthanizing humans to examine their brains, and asks you how we learn about adolescent human brains. What can you tell her about how human brains are studied?

Scientists can use fMRI (functional magnetic resonance imaging), DTI (diffusion tensor imaging), and EEG (electroencephalography) techniques to study brain growth and changes in brain chemistry. fMRI, a noninvasive procedure, is used to look at activity in brain regions during performance of various tasks, and can be used to compare adolescents and adults on the same task. DTI is also noninvasive and can be used to compare the connections made by the brain in adolescents and adults. EEG measures electrical activity at different locations on the scalp. EEG can be used to examine changes in electrical activity (event related potentials [ERP]) in response to different stimuli or events. Scientists often compare ERPs between people of different ages to determine when/if patterns of brain activity undergo developmental change. Other techniques include studying brain growth and development in other animals, studies of changes in brain chemistry in humans and other species, and postmortem studies of brain anatomy.

Key Points:

- a) fMRI, DTI, and PET are useful for studying changes in brain growth and brain chemistry.
- b) fMRI allows comparison of brain activity.
- c) DTI allows comparison of brain connections.
- d) EEG allows comparison of electrical activity.

106. Fifteen-year-old Randall was a participant in a research study on risk taking. According to his answers on the survey, Randall understands the dangers of drinking and driving, having unprotected sex, and using marijuana. However, at a party last week, Randall was seen smoking marijuana and getting into a car with an intoxicated driver. How would you explain this inconsistency in Randall's behavior in terms of the four main aspects of brain development? Obviously, he knows the right answers, yet he engages in risky behavior.

1. Synaptic pruning—unused connections between neurons are eliminated, but different regions of the brain are pruned at different points in development. During adolescence the prefrontal cortex (PFC) is pruned, making more efficient pathways for information processing. Because Randall is 15, he is not likely to have completely finished undergoing PFC synapse pruning.
2. Myelination—Related to the idea of synaptic pruning is the myelination of the preserved neurons. This process, which involves covering parts of neurons in myelin (fat) sheaths, makes information transfer quicker and more efficient.
3. Changes in neurotransmitters in the limbic system—Notably, changes in how the brain is affected by dopamine and serotonin, two neurotransmitters, can make adolescents like Randall more emotional and responsive to stress or

rewards. This too contributes to Randall's risk-taking behavior—he is highly concerned with what his peers think of him and his limbic system is motivating him to take greater risks in order to relieve boredom.

4. Frontal lobe maturation—the prefrontal cortex is also maturing at this point in Randall's life. The PFC is not finished maturing until the mid-20s, so 15-year-old Randall may have some advanced cognitive skills relative to his preadolescent self, but he is not yet fully mature. This, too, explains the discrepancy in his understanding of right and wrong and his choices to make risky decisions. Also, changes in the limbic system occur at puberty, though the PFC, the part of the brain that is responsible for decision making, planning ahead, and controlling impulses, is not fully mature until the age of 25 or so.

Key Points:

- a) Synaptic pruning (name and define)
- b) Myelination (name and define)
- c) PFC maturation (name and define)
- d) Changes in neurotransmitters (name and define)
- e) Relate all four changes to Randall's current risk-taking behavior.
- f) Gap in timing between limbic system and prefrontal cortex

107. In what five ways are the intellectual abilities of adolescents superior to those of children? Explain and give a concrete illustration of each developmental trend.

There are five chief ways in which the thinking of adolescents is more advanced, more efficient, and more effective than that of children. First, during adolescence individuals become better able to think about what is possible, instead of limiting their thought to what is real or directly observable. Second, adolescents become better able to think about abstract things, rather than being limited to the concrete. Third, during adolescence individuals begin thinking more often about the process of thinking itself. Fourth, adolescents' thinking tends to become multidimensional, rather than limited to a single issue. Finally, adolescents are more likely than children to see things as relative, rather than absolute. Several examples of each of these trends are given in the text.

Key Points:

- a) Think about what is possible.
- b) Think about abstract concepts.
- c) Think about thinking—metacognition.
- d) Thinking is multidimensional.
- e) See things as relative rather than absolute.

108. Describe a class that Lev Vygotsky would teach. What components would be important in his classroom? What tactics would the teacher employ to facilitate learning?

Vygotsky argued that children and adolescents learn best in their zone of proximal development, or in everyday situations when they encounter tasks that are neither too simple nor too advanced, but just slightly more challenging than their abilities permit them to solve on their own. The role of the teacher is to "scaffold," or to help structure the learning situation so that it is within reach of the student. Therefore, Vygotsky would use real-life examples, and have students practice what they learn. For example, a class on amphibians might take place at a local pond.

Key Points:

- a) Zone of proximal development
- b) Role of the teacher is to scaffold.
- c) Use real-life examples to have students practice what they learn.

109. Steve gets all As in his course work but has a hard time relating to the real world. Jessica has been failing her courses but is an exceptional artist. The guidance counselor, Miss Willingham, has stated that Steve is "smarter" than Jessica. Do you agree or disagree with Miss Willingham's conclusion? Support your answer.

I disagree with Miss Willingham's conclusion. Sternberg's triarchic theory of intelligence shows that intelligence consists of three different components: (1) componential - school smarts, (2) experiential - creativity and insight, and (3) contextual - street smarts. Steve excels in the componential aspects of intelligence but falls behind in the contextual

aspects of intelligence. Jessica excels in the experiential aspect of intelligence but falls behind in the componential area. Each is more skilled in a certain aspect of intelligence and less skilled in another. Because no single aspect of intelligence is more important than another, it is not a valid conclusion to state that Steve is smarter than Jessica or vice versa.

Key Points:

- a) Sternberg's triarchic theory of intelligence would lead us to disagree.
- b) Steve exhibits componential aspects (school smarts).
- c) Jessica exhibits experiential aspects (creativity and insight).

Page: 61

110. Nicole is an adolescent and has experienced changes in cognition and theory of mind capacities. Her mom and dad believe that these changes have both positively and negatively influenced their relationship with their daughter. How would an adolescent development psychologist explain the effects of these normative developmental changes in cognition?

With age, adolescents develop a more sophisticated theory of mind, which is the ability to understand that others have beliefs, intentions, and knowledge that may be different from one's own. With this advancement, they are better able to interpret the feelings of others and to infer their motives and feelings, even when specific information is not directly observable. Additionally, adolescents experience considerable improvements in their ability to view events from the perspective of others (Nicole will also be more able to understand her parents' perspective on her own point of view). These gains also allow her to improve in communication, as she is more capable of formulating arguments in terms that are more likely to be understood by her parents (people whose opinion might be different). As Nicole is better able to see more things from her parents' point of view and to infer the motives/intents behind her parents' opinions, Nicole's parents may have noticed a positive change in their relationship. Although there are advancements in the ability to see things from other vantage points, these improvements also lead to changes in the way in which adolescents think about relationships with parents and transform their beliefs about authority.

With age, adolescents increasingly distinguish between moral issues and conventional issues, and between which issues authority figures have the right to regulate and issues that are their own personal choice. As adolescents begin to make these distinctions, they may come to question their parent's authority in various contexts. Issues that had been viewed as matters of right and wrong start to seem like matters of personal choice (and beyond the boundaries of parental control). Additionally, Nicole's parents might believe their relationship quality has declined because Nicole has become more argumentative. Research indicates that adolescents are better able than young children to envision and therefore anticipate the possible responses of an opponent and to have handy counterarguments available. This means that Nicole is probably a better arguer than she was as a child. Finally, as Nicole experiences changes in the way in which she thinks, she will stop accepting other people's view without questioning. Because Nicole will shift from seeing things in absolute terms to seeing things as relative, she will be more likely to question others' assertions and less likely to accept facts as absolute truths (this increase in relativism might cause her parents to think that Nicole is questioning everything for the sake of argument). Nicole's advancement in social cognition will also result in Nicole becoming better at telling lies.

Key Points:

- a) Define theory of mind.
- b) Explain why understanding parents' perspective might positively influence parent-child relationships and communication.
- c) Explain why understanding parents' perspective taking may lead to changes in Nicole's beliefs about authority.
- d) Explain why Nicole might become more argumentative during adolescence.

Page: 62

111. Anita cannot understand why adolescents are more likely than any other age group to engage in risky behaviors. She has learned in class that individuals undergo significant cognitive advancements during adolescence, and in fact, many adolescents aged 15 and older use the same basic processes that adults use to make decisions. Your instructor has asked you to explain to Anita why risk taking may peak during adolescence. What do you tell her?

Data indeed indicate that adolescents are more likely than any other age group to engage in risky behaviors (reckless driving, unprotected sex).

When asked under calm, laboratory tasks, adolescents are well aware of the dangers associated with many risky behaviors. In fact, there is no evidence that adolescents are worse at perceiving risks than adults are and many studies have indicated that adolescents' decision making is as good as adults' when individuals are tested under calm conditions. However, in the real world, opportunities to engage in risky behaviors usually occur when adolescents are

emotionally aroused and/or with their peers. In these contexts, adolescent decision making is likely to be compromised. Furthermore, though adolescents and adults may respond very similarly on logical reasoning tests, adolescents are more susceptible to peer influence, less future oriented, more reward seeking, and more impulsive than adults—all of which may contribute to risk taking. Also, adolescents pay more attention to the potential rewards of engaging in a risky behavior than adults do.

Research has indicated that there may be biological underpinnings for some adolescent risk taking. For example, the gap between the relatively late timing of the prefrontal cortex (it is not mature until about 25 years of age) and the relatively early changes in the limbic system (usually around pubertal onset), may provoke the adolescent to seek novelty, reward, and excitement years before the region of the brain that manages and controls judgment and decision making is fully mature.

Key Points:

- a) Adolescents engage in more risk taking than children and adults.
- b) Adolescents may respond to risky behaviors questionnaires like adults when asked under calm situations.
- c) Risk taking in the real world is influenced by emotional and contextual factors.
- d) Gap between prefrontal cortex maturation and changes in the limbic system may contribute to risk taking.
