

Chapter 2 Solutions

- 2.1 (a) VHDL - VHSIC Hardware Description Language
VHSIC - Very High Speed Integrated Circuit
- (b) VHDL has statements that execute concurrently since it must model real hardware in which the components are all in operation at the same time.
- (c) A hardware description language allows a digital system to be designed and debugged at a higher level of abstraction than schematic capture with gates, flip-flops, and standard MSI building blocks. The details of the gates and flip-flops do not need to be handled during early phases of design. Designs are more portable when low-level library-specific details are not included in the model. HDLs allow the creation of such portable high-level behavioral models.
- 2.2 (a) Legal: A_123, and1; Illegal: 123A (Starts with number), _A123 (starts with underscore), A123_ (ends with underscore), c1__c2 (adjacent underscores), and (reserved word).
- (b) They all equivalent. VHDL is not case sensitive.

2.3 (a)

(b)

```

2.4 entity Comb is
    port(A, B, C, D : in bit;
          Z : out bit);
end Comb;

architecture Comb2_1 of Comb is
    signal E, F, G, H, I : bit;
begin
    H <= (A and B and C) after 5 ns;
    E <= H or D after 5 ns;
    G <= (B nor C) after 5 ns;
    F <= G nand A after 5 ns;
    I <= not F after 2 ns;
    Z <= E xor I after 5 ns;
end Comb2_1;
  
```

```

2.5 (a) entity one_bit_sub is
    port(x, y, bin: in bit;
          diff, bout: out bit);
end one_bit_sub;

architecture equ of one_bit_sub is
begin
    diff <= x xor y xor bin; -- difference. See problem 1.2 answer
    bout <= (not x and bin) or (not x and y)
              or (bin and y); -- borrow out. See problem 1.2 answer
  
```

```
end equ;
```

```
(b) entity four_bit_sub is
    port(a, b: in bit_vector(3 downto 0);
          bin: in bit;
          d: out bit_vector(3 downto 0);
          bout: out bit);
end four_bit_sub;

architecture test of four_bit_sub is
    signal bo: bit_vector(3 downto 0) := "0000"; -- borrow bits
    component one_bit_sub
        port(x, y, bin: in bit;
              diff, bout: out bit);
    end component;
begin
    FS0: one_bit_sub port map(a(0),b(0),bin,d(0),bo(1));
    FS1: one_bit_sub port map(a(1),b(1),bo(1),d(1),bo(2));
    FS2: one_bit_sub port map(a(2),b(2),bo(2),d(2),bo(3));
    FS3: one_bit_sub port map(a(3),b(3),bo(3),d(3),bout);
end test;
```

2.6 (a) entity circuit is

```
    port(A, B, C, D: in bit;
          G: out bit);
end circuit;

architecture internal of circuit is
    signal E, F: bit;
begin
    E <= A and B;
    F <= E or C;
    G <= D and F;
end internal;
```

(b) entity circuit is

```
    port(A, B, C, D: in bit;
          G: out bit);
end circuit;

architecture internal of circuit is
    signal E, F: bit;
begin
    process(A, B, C, D, E, F)
    begin
        E <= A and B;
        F <= E or C;
        G <= D and F;
    end process;
end internal;
```

2.7 A changes to 1 at 25 ns, B changes to 1 at $20 + \Delta$ ns, C does not change

2.8 (a) A falling-edge triggered D flip-flop with asynchronous active high clear and set

(b) Q = '0', because Clr = 1 has priority.

2.9 entity SR_Latch is

```
    port(S, R: in bit;
          Q, Qn: inout bit);
end SR_Latch;
```

```

architecture proc of SR_Latch is
begin
  process(S, R)
  begin
    if S = '1' then Q <= '1'; end if;
    if R = '1' then Q <= '0'; end if;
  end process;
  Qn <= not Q;
end proc;

```

2.10 entity MNFF is

```

  port(M, N, CLK, CLRn: in bit; Q: inout bit; Qn: out bit);
end MNFF;

```

architecture MN of MNFF is

```

begin
  process(CLK, CLRn)
  begin
    if CLRn = '0' then Q <= '0';
    elsif CLK = '0' and CLK'event then
      if M = '0' and N = '0' then Q <= not Q;
      elsif M = '0' and N = '1' then Q <= '1';
      elsif M = '1' and N = '0' then Q <= '0';
      elsif M = '1' and N = '1' then Q <= Q; --optional
      end if;
    end if;
  end process;
  QN <= not Q;
end MN;

```

2.11 entity DDFD is

```

  port(R, S, D, Clk : in bit;
        Q : out bit);
end DDFD;

```

architecture Behav of DDFD is

```

begin
  process(Clk, R, S)
  begin
    if R = '0' then Q <= '0';
    elsif S = '0' then Q <= '1';
    elsif Clk'event then Q <= D;
    end if;
  end process;
end Behav;

```

2.12 (a) entity ITFF is

```

  port(I0, I1, T, R: in bit;
        Q, QN: inout bit);
end ITFF;

```

architecture behavior of ITFF is

```

begin
  process(T, R)
  begin
    if R = '1' then
      Q <= '0' after 5 ns;
    else

(b) The block diagram is similar to Figure 2-47 with an "Up" input added to each counter. The VHDL description similar to Figure 2-48.

- 2.32** Students should look on the web for 74192 data sheet. CLR is active high. LOADB is active low. Counting up happens when UP has a rising edge and DOWN=1. Counting down happens when DOWN has a rising edge and UP=1. CARRY indicates terminal count in the up direction, i.e. 9. BORROW indicates terminal count in the down direction, i.e. 0.

Operating Mode	CLR	LOADB	UP	DOWN	D	Q	Borrow	Carry
Clear	1	X	X	0	XXXX	0000	0	1
	1	X	X	1	XXXX	0000	1	1
Load	0	0	X	X	XXXX	Q = D	1*	1*
Count Up	0	1	↑	1	XXXX	Q = Q + 1	1	1**
Count Down	0	1	1	↑	XXXX	Q = Q - 1	1**	1

* when loading, if the input is 0 and down = 0, borrow will be 0. If the input is 9 and up = 0, carry will be 0

** Borrow = 0 when the counter is in state 0 and down = 0. Carry = 0 when the counter is in state 9 and up = 0.

```

elsif ((x1&x2) = "01") **then** next_state <= 2 **after** 10 ns;
else next_state <= 1 **after** 10 ns; **end if**;
 when 2 => **if** ((x1 & x2) = "00") **then** next_state <= 2 **after** 10 ns;
elsif ((x1&x2) = "01") **then** next_state <= 1 **after** 10 ns;
else next_state <= 3 **after** 10 ns; **end if**;
 when 3 => **if** ((x1 & x2) = "00") **then** next_state <= 1 **after** 10 ns;
elsif ((x1&x2) = "01") **then** next_state <= 2 **after** 10 ns;
else next_state <= 3 **after** 10 ns; **end if**;
 end case;
 end process;
 process(clk)
 begin
if (clk = '0' **and** clk'event) **then**
 state <= next_state **after** 5 ns; **end if**;
 end process;
 z1 <= '1' **after** 10 ns **when** state = 2 **else** '0' **after** 10 ns;
 z2 <= '1' **after** 10 ns **when** state = 3 **else** '0' **after** 10 ns;
end behavioral;

2.41 (a) *nextstate* is not always assigned a new value in the conditional statements, else clauses are not specified. so a latch will be created to hold *nextstate* to its old value.

(b) The latch output would have the most recent value of *nextstate*.

(c) **process**(state, X)
begin
 case state **is**
 when 0 => **if** X = '1' **then** nextstate <= 1;
else nextstate <= 0; **end if**;
 when 1 => **if** X = '0' **then** nextstate <= 2;
else nextstate <= 1; **end if**;
 when 2 => **if** X = '1' **then** nextstate <= 0;
else nextstate <= 2; **end if**;
 end case;
end process;

2.42

Signal or Variable	time	new value
A	20 ns	1
F	20 ns	6
A	20 ns	6
B	25 ns	7
C	30 ns	2
D	35 ns	5

Note: The change to A=1 is never visible.

2.43 *Sel* should be a variable, instead of a signal. Otherwise *sel* will not update for current use. It updates only at the end of a process so the case statement will get the wrong value.

2.44

ns	Δ	A	B	D
0	+0	0	0	0
5	+0	1	0	0
15	+0	1	0	1
15	+1	1	1	1
25	+0	1	1	0
25	+1	1	0	0
35	+0	1	0	1
35	+1	1	1	1
40	+0	0	1	1

Lab Assignment #2

Guideline

This lab is to be done individually. Each person does his/her own assignment and turns it in.

Objective

To learn designing basic sequential circuits in VHDL and implementing them on an FPGA.

Problem 1: Excess-3 code converter design

In this problem, you will be designing an FSM using three different styles of VHDL coding: behavioral, dataflow, and structural. The following is the problem for which you will be designing the FSM:

A sequential circuit has one input (X), a clock input (CLK), and two outputs (S and V). X , S and V are all one-bit signals. X represents a 4-bit binary number N , which is input least significant bit first. S represents a 4-bit binary number equal to $N + 3$, which is output least significant bit first. At the time the fourth input occurs, $V = 1$ if $N + 3$ is too large to be represented by 4 bits; otherwise, $V = 0$. The value of S should be the proper value, not a don't care, in both cases. The circuit always resets after the fourth bit of X is received. Assume the sequential circuit is implemented with the following state table. The outputs are (S, V). All state changes occur on the falling edge of the clock pulse.

Present State	Next State		Output	
	X=0	X=1	X=0	X=1
S0	S1	S2	1,0	0,0
S1	S3	S4	1,0	0,0
S2	S4	S4	0,0	1,0
S3	S5	S5	0,0	1,0
S4	S5	S6	1,0	0,0
S5	S0	S0	0,0	1,0
S6	S0	S0	1,0	0,1

- a. Write a *behavioral VHDL description* using the state table shown above. Compile and simulate your code using the following test sequence:

$X = 1011\ 1100\ 1101 \leftarrow$

The first input bit is at the far right. This is the LSB of the first 4-bit value. Therefore, you will be adding 3 to 13, then to 12, and then to 11. While simulating, keep the period of the CLK to be 10ns. Change X 1/4 clock period after the rising edge of the clock.

- b. Write a *data flow VHDL description* using the next state and output equations to describe the state machine. You can use Logic Aid to derive the logic equations. Assume the following state assignment:

$S0 = 000, S1 = 010, S2 = 001, S3 = 101, S4 = 011, S5 = 100, S6 = 111$

Compile and simulate your code using the same test sequence and timing as (a).

- c. Write a *structural model* of the state machine in VHDL that contains the interconnection of gates and D flip-flops. Compile and simulate your code using the same test sequence and timing as (a).

Problem 2: BCD Counter Design

Implement a 1 digit BCD (binary coded decimal) counter. It should be a synchronous (4-bit) up/down decade counter with output Q that works as follows: All state changes occur on the rising edge of the CLK input, except the asynchronous clear (CLR). When $CLR = 0$, the counter is reset regardless of the values of the other inputs. You can keep the time period of the CLK signal to 10ns for simulating your design.

If the $LOAD = ENABLE = 1$, the data input D is loaded into the counter.

If $LOAD = 0$ and $ENABLE = UP = 1$, the counter is incremented.

If $LOAD = 0$, $ENABLE = 1$, and $UP = 0$, the counter is decremented.

If $ENABLE = 1$ and $UP = 1$, the carry output (CO) = 1 when the counter's value is 9.

If $ENABLE = 1$ and $UP = 0$, the carry output (CO) = 1 when the counter's value is 0.

- a. Write a VHDL description of the counter. You may implement your design in any style you wish. It will be easier to use a behavioral description which can be either written in the algorithmic way (eg. $Count \leq Count + 1$ – Figure 2.46 in the text) or a state machine way (eg. $State \leq Next_State$ – Figure 2.54/2.56 in the text). You may also use dataflow or structural descriptions, although that will be more work. Use the following simulation for your waveforms:

1. Load counter with 6
2. Increment counter four times. You should get 9 and then 0.
3. Decrement counter once. You should get 9.
4. Clear the counter.

- b. Write a VHDL description of a decimal counter that uses two of the above counters to form a two-decade decimal up/down counter that counts up from 00 to 99 or down from 99 to 00. In other words, instantiate (port map) two single digit counters in a top module (the two-digit counter). You may need some extra logic in the top module too other than these instantiations. The top module will have these inputs and outputs: CLR , CLK , $ENABLE$, $LOAD$, UP , $D1$, $D2$, $Q1$, $D2$, CO . Use the following simulation for your waveforms:

1. Load counter with 97
2. Increment counter five times.
3. Do nothing for 2 clock periods
3. Decrement counter four times.
4. Clear the counter.

Problem 3: Synthesizing and implementing the BCD counter on the FPGA

Use the code for the single digit BCD counter that you wrote in Problem 2a. Before you synthesize it and implement it on the board, you will have to modify your code a little bit. This is because the CLK signal available on the board is a high frequency signal (50 MHz). If you use this high frequency for your circuit, you will not be able to give proper inputs or see proper outputs to your design.

So, you need to add a clock divider to your VHDL description. Create two more entities in your design. Call one as *top* and another as *divider*. Make connections as shown in the following figure. Look at the codes given in the end of this document, understand them and see how they can be used as clock dividers.

Ensure that there are no latches in your design. Xilinx ISE will report these in the Synthesis report. You need to eliminate such warnings. You may want to read the synthesis guidelines “Tips for writing synthesizable code” available on Blackboard.

To look for latches in your synthesized design, open the synthesis report generated by ISE by clicking “View Synthesis Report” under the “Synthesize-XST” option. In the synthesis report, look for “Macro Statistics” and see if any latches are being shown. Alternatively, you can look for “cell usage” in the report and there should not be any cells under “Flip Flops/Latches” having names starting with “L”.

Also, after adding the counter/clock divider block to your design, simulate the top entity in Modelsim before directly synthesizing using ISE to ensure that the counter/divider works. And while simulating, reduce the large values (like 5000000) in the counter to small values (say 50), so that simulation takes less time and the waveforms are legible. Don't forget to switch to the correct (large) value before synthesizing.

Synthesize the top module (which includes the divider and the 1-digit bcd counter) and use the following pin assignments. Download the design onto the board and make sure it works as expected.

LOAD	BTN0
D	SW[3:0]
ENABLE	SW4
UP	SW5
CLK	B8
COUNT	LED[3:0]
CO	LED4

CLR	SW6
-----	-----

Useful Information

1. Don't limit your testing to the input sequences mentioned with the problem statement. During the checkouts, the TAs will apply several input combinations to test your design. So, make sure to do a thorough testing of your design using sufficient number of inputs.
2. While simulating your design, it is always a good idea to stagger your inputs with respect to the active clock edge. For example, if your active clock edge is occurring at 10ns, apply your inputs sometime before 10ns, say at 8ns. This ensures that when your design was clocked, the input was successfully read. If your active edge occurs at 10ns and your input also changes at 10ns, then it becomes hard to see whether the input was successfully captured by the clock edge or not.

3. A state machine can be designed using either a single process statement (like Figure 2.56 in the text) or using two process statements (like Figure 2.54 in the text). Both ways are correct. However, it is easier to design it using a single process statement. Generally, the single process statement partakes less debugging effort. This is good guideline to observe during the entire semester.

Submission Details

All parts of this lab are to be submitted on Blackboard. No hard-copy submission is needed. For each problem, please zip all your files into a single folder with the following naming scheme: *Lastname_Problem#.zip*

Problem	Submission Requirements
1	<ul style="list-style-type: none"> • VHDL file(s) • Do-file
2	<ul style="list-style-type: none"> • VHDL file(s) • Do-file
3	<ul style="list-style-type: none"> • VHDL file(s) • Bit-file and UCF File

Checkout Details

During your checkout you will be expected to demonstrate each of the problems in the assignment and answer verbal questions about the assignment.

Example 1

```
library IEEE;
use IEEE.numeric_bit.ALL;

entity simpleCounter is
    Port ( clk50Mhz : in bit;
          led : out bit);
end simpleCounter;

architecture Behavioral of simpleCounter is
    signal counter: unsigned (26 downto 0);
    signal cnt_temp: bit_vector(26 downto 0);
begin

    process (clk50Mhz)
    begin
        if clk50MHZ = '1' and clk50Mhz'event then
            counter <= counter + 1;           --increment counter every 20 ns (1/ 50 Mhz) cycle.
        end if;
    end process;

    cnt_temp <= bit_vector(counter);
    led <= cnt_temp(26);                     -- (2^26 / 50E6) = 1.34 seconds

end Behavioral;
```

Example 2

```
library IEEE;
use IEEE.numeric_bit.ALL;

entity complex is
    Port ( clk50Mhz : in bit;
          led : inout bit
          );
end complex;

architecture Behavioral of complex is
    signal counter: integer range 1 to 50000000;
begin

    process (clk50Mhz)
    begin
        if clk50MHZ = '1' and clk50Mhz'event then
            if counter = 50000000 then counter <= 1; led <= not led;
            else counter <= counter + 1;
            end if;
        end if;
    end process;
